The metallic bonding is a special type of bonding that holds metals together in the metal crystal. This bond is neither covalent nor ionic. Metals tend to yield electrons and no one is to accept them. There are several theories to explain this type of bond, including the model of the sea of electrons is the most popular. The model of the sea of electrons Some characteristics of metals are the reasons behind the metal bond. Metals have low ionization energy; This means that metals can easily release their valence electrons. We know that ionization energy increases from left to right during the period and decreases in the group in the periodic table. Metals have full orbits in half. As for example, the electronic configuration of the sodium is 1S22S22P63S1. Thus the sodium has half filled orbital s. Explanation of the model of the sea of electrons Due to the low energy of ionization, the metal valence electrons are freely bound within the atom. The semi-filled orbitals of adjacent metals can overlap between them in the metal crystal. The electrons connected freely can move freely in these orbits to delocalize the whole crystal. So the positive metallic ions stick together due to their electrostatic force among the nearby positive ions for the delocalized electrons. The positive ions are immersed in the sea of electrons. This is why this model is known as the model of the sea of electrons. Example Sodium has a valence electron. This electron can delocalize through the metal crystal to form the metal bond. And the positive atom of sodium immersed in the sea of delocalized electrons. The 3D model of the sodium is as follows: Explanation of the physical properties of metal by metal bonding The metallic bond (electronic sea model) can explain the physical properties of metals. For example, 1. Ductility and malleability Ductility is metal property for what you can apply stress on a metal to make it longer or wider without breaking. Here (a) is fragile, (b) is partially ductile and (c) is completely ductile in nature. A Malleability It is another similar physical property of metals, where metals can be deformed under global effort. It can be measured by hammering or rolling a metal to form a sheet or any other desired shape. The ability of this deformation depends on the temperature. For example, gold has a high ductility and malleability. So beautiful form of gold jewelry is available in the market. These metal properties can be explained by the model of the sea of metal bond electrons. When a metal is solicited by a hammer or in any other way the internal structure of the metal crystals remains unchanged. The sea ofAnd positive ions regulate their position accordingly to restore the crystalline structure of stressed metal. This allows the metal to be ductile and malleable. 2. Heat conductor Metals are good heat conductors. When one side of a metal is heated, the other metal end becomes warm. The electrons in the metallic bond in the heated heated part Heat and vibrate. Switch the energy for the next electrons and therefore the thermal energy leads to the end. 3. Electric metal conductors are also good electricity conductor. We can get electricity, when the electrical voltage is applied to the metal wire. Metal mobile electrons can move freely in the specific direction when the voltage applied. The best electricity conductors are those metals that has a minimum attraction for the Mantuan Electrons. 4. Photoelectric metal effect show photoelectric effect. When the sufficient thermal energy is applied to a metal, the electrons are emitted by the metal crystal. The free metal electrons absorb thermal energy necessary to overcome the attractive force inside the metal crystal and then emitted. 5. Metals Reflection can reflect the light. Electrons in a metal can absorb particular light wavelength to switch to the highest energy level. When it comes to the initial state, it emits the same wavelength of light. Like the wavelength of incident light is the same light emitted, let's see how reflection of light. 4.43 / 5 (28) Which is indicated the quality level based on complexity./ Goe LD of the word / precious yellow metallic element, highly malleable and ductile, and not subject to oxidation or corrosion.
