[1] Symptoms generally includes pain at the base of the thumb that is worse, with the use of the hand. [2] Anatomical tobacchira is generally tender and swelling can occur. [2] Complications can comprise pseudoarthrosis of fracture, avascular necrosis of the proximal part of the bone, and arthritis. [2] [1] Scaphoid fractures are more commonly caused by a fall on the tense hand. [2] The diagnosis is generally based on a combination of clinical examination and medical imaging. [2] Some fractures may not be visible to claring x-rays. [2] In such cases the affected area can be immobilized in a splint or cast and review with X-ray repetition in two weeks, or alternatively a magnetic resonance or bone scintigraphy can be performed. [2] The fracture can be prevented using cuffs during some activities. [1] In those in which the fracture remains well aligned a cast is generally sufficient. [2] If the fracture is moved so it is generally advisable surgery. [2] Healing can take up to six months. [1] It is the most commonly fractured carpal bone. [3] Males are struck more often than females. [2] ANATOMIC SIGNS AND SYMPTOMS Tobaccocone People with scaphis fractures generally have tobacchir Foot tenderness is generally present in one of three positions: 1) fly prominence at the distal wrist for polar distal fractures; 2) anatomical snuff box for life or midbody fractures; 3) distal to Lister tubercle for polar proximal fractures. [4] Scaphoid complications before and after treatment with Herbert screw. The vascular supply of the hull comes from two different vascular pedicles. 20-30% of blood supply (a.) comes from the volar branch of radial artery and enters the bone to the tubercle. 70-80% comes from (b.) the dorsal branch of radial artery and travels towards the proximal pole. The avascular necrosis (AVN) is a complication of the scaphoid fracture. Since the hull receives its arterial supply retrogradely (i.e. from the distal pole to the proximal pole), the proximal part to the fracture is usually influenced. [5] The risk of AVN depends on the position of the fracture. Fractures in the third proximal have a high incidence of AVN (~30%) Life fractures in the third medium are the most frequent fracture site and have a moderate risk of AVN. Fractures in the third space are rarely complicated by AVN. Non-unional can also occur from undiagnosed or underrated hull fractures. The arterial flow to the hull enters through the distal pole and travels to the next pole. This blood stream is soft, increasing the risk of non-union, especially with fractures on the wrist and proximal ends. [4] If not properly treated the non-union of the hull fracture can lead to the osteoarthritis of the wrist. Symptoms may include wrist pain, decrease in the range of wrist movement, and pain during activity such as lifting or taking. If x-ray results show arthritis due to an old break, the treatment plan will first focus on treating arthritis through anti-inflammatory drugs and wearing a splint when an individual feels wrist pain. If these treatments do not help the symptoms of arthritis, the wrist steroid injections can help relieve pain. If these treatments do not work, surgery may be required. [6] Discard fractures occur in three positions: (A) Distal Tubercular, (B) Life and (C) Proximal pole. Fractures of scaphoids may occur either with direct axial compression or with hyper-extension of the wrist, such as a fall on the palm on an external fracture. [7] In the Herbert classification system, there are three main types of hull fractures. 10%-20% of the fractures are at the next pole, 60%-80% is alive (middle), and the rest occurs at the pole. [4][7] [8] Fracture of the throttle of the pulse hull bone The fractures of the capoids are often diagnosed using simple X-rays and multiple views are obtained as standard. [9] However, not all fractures are evident initially [7] Therefore, people with tenderness over the hull (those that expose pressure pain in the anatomical box of the buttocks) are often splicing in a thumbhole for 7-10 days to which a second set of X-rays is taken. [7] If initiallypresent a minimally displaced fracture, healing will be evident. Even then, a fracture may not be obvious. A CT scan can then be used to evaluate the scaphoid with a higher resolution. The use of MRI, if available, is preferred preferred preferred Ct and can give an immediate diagnosis. [10] Bone scintigraphy is also an effective method for fracture diagnosis that do not appear on Xray. [11] A thin scaphoid fracture a more obvious scaphoid fracture on a radiosouction of the X Ray Ray Radioluction scaphoid around a 12-day scaphoid fracture that was initially barely barely visible. [12] Treatment of scaphoid fractures is guided by the position in the bone of the fracture (next, waist, distal), displacement (or instability) of the fracture, and the patient's tolerance for spindle immobilization. (Quotation required) for non- and minimally displaced fractures (up to 2 mm)) of the life of the scaphoid, immobilization fusion (with surgical fixation for non-untette fractures at 6 to 12 weeks) is effective as an immediate fixation of the surgery. This was demonstrated by the Sviff study (Internal fixation of the scaphoid life for fracture testing), 439 patients were randomly assigned to embedded in fusion or surgical fixation. There was no difference in healing, pain and function or working days between the two treatment groups, the cast immobilization group had fewer complications and this treatment was cheaper. [13] [14] The choice of the short arm, the short arm of the thumb or the cast of the long arm is discussed in the medical literature and no clear consensus or evidence of the benefit of one type of fusion or another has been demonstrated; Although it is generally accepted to use a short arm or a short thumb Spica arm for non-displaced fractures. [7] In the Swift study used more a short arm with the thumb left free. The non-displaced or threatened minimally displaced fracture can also be treated with percutaneous surgery or minimal incision which, if performed correctly, has a high left rate, low morbidity and a faster return to activity than closed flow management. [15] However, this was not confirmed by the Swift study. [13] [14] fractures that are more proximate take longer to heal. The distal third is expected to heal between 6 and 8 weeks, the middle third will require 8 Å 12 weeks and the proximal third will require 12 Å 24 weeks. [7] [8] The scaphoid receives its blood supply mainly from the lateral and distal branches of the radial artery. Blood flows from the upper/distal end of the bone in a retrograde fashion to the proximal pole. If this blood flow is interrupted by a fracture, the bone may not heal. Surgery is required at this point to mechanically repair the bone together. [Quotation required] Percutaneous screw fixation is recommended on an open surgical approach when it is possible to obtain an acceptable closed bone alignment as minimal incisions can preserve Complex of the handheld ligament and local vascularization, and helps avoid soft tissue complications. This surgery includes screwing the scaphoid bone together with the most perpendicular angle possible to promote rapid and stronger healing of the bone. Internal fixation can be performed dorsally with a percutaneous incision and arthroscopic assistance [16] or through a minimum open dorsal approach, [15] or or A flying approach in which a slight excavation of the bone of the trapeze bone can be needed to reach the scaphoid as 80% of this bone is covered with articular cartilage, which makes it difficult to access the scaphoid. [17] Epidemiology fractures of the scaphide are common in young males. [18] They are less common in children and adults greater because the distal radius is weaker than the wrist and more likely to get fractured in these groups of age. [7] Caphoid fractures represent 50% -80 of carpal lesions. [8] Terminology These are also called marine fractures (the scaphide is also called carpal navicular), even if this can be confused with the maritime bone in the foot.
